INTRODUCTION

The current paper continues the study on Coleoptera fauna of Naujene rural municipality. In previous parts, 166 species representing 28 families (Bukejs 2006) and 254 species representing 17 families (Bukejs & Telnov 2007) were mentioned.

There are new faunistical data on 210 species belonging to 38 families of Coleoptera presented in this paper.

MATERIALS AND METHODS

The material was collected since 2000 till 2011 in different places of Naujene rural municipality (Daugavpils district, Latvia) (Fig.1). In this

area various habitats were investigated: forests (coniferous, deciduous and mixed), forest edges, clearing, burnt area, valley and bank of river Daugava (part of Nature Park “Daugavas Loki”), bank of Lake Lielais Stropu, ponds, meadows (xeric and humid), agrocenosis, park, anthropogenic habitats and others.

Beetles were collected using different entomological methods: entomological net, pit-fall traps, windows traps, visual observation of habitats (on soil, on plants, under different objects etc.), caught by hand, and collecting in hibernation places. A total of 859 specimens of Coleoptera were processed in the current research. The reviewed material is deposited in the collection of the Daugavpils University Institute of Systematic Biology (DUBC,

Daugavpils, Latvia), the private collection of Dmitry Telnov (Rīga, Latvia), and the private collection of author (Daugavpils, Latvia).

The systematics used follows that suggested by Silfverberg (2004).
